---

1. Consider the following inference rules that define the relation  $\rightsquigarrow$ , which is a subset of  $\mathbb{N} \times \mathbb{N}$ .

$$\frac{a \rightsquigarrow b}{c \rightsquigarrow d} \quad c = a + 1 \text{ and } d = b + 2 \qquad \frac{}{0 \rightsquigarrow 0}$$

Which *one* of the following statements is true?

- a) For all  $(a, b) \in \rightsquigarrow$ ,  $b$  is equal to  $2^a - 1$ .
- $\Rightarrow$  b) For all  $(a, b) \in \rightsquigarrow$ ,  $b$  is even.
- c) The relation  $\rightsquigarrow$  is reflexive.
- d) For all  $(a, b) \in \rightsquigarrow$ ,  $a$  is greater than or equal to  $b$ .

2. Consider the set **GG** given by the following inference rules.

$$\frac{}{\text{raas} \in \mathbf{GG}} \qquad \frac{}{\text{fusion} \in \mathbf{GG}} \qquad \frac{d \in \mathbf{GG} \quad e \in \mathbf{GG}}{(\text{senior}, d, e) \in \mathbf{GG}}$$

Suppose we want to prove that some property  $P$  holds of every element of **GG**.

Which *one* of the following is an appropriate inductive reasoning principle?

- a) If  $\forall a_1, a_2 \in \mathbf{GG}. P(a_1) \wedge P(a_2) \implies P((\text{senior}, a_1, a_2))$  then  $\forall a \in \mathbf{GG}. P(a)$ .
- b) If  $P(\text{raas})$  and  $P(\text{fusion})$  and  $P((\text{senior}, \text{raas}, \text{fusion}))$  then  $\forall a \in \mathbf{GG}. P(a)$ .
- $\Rightarrow$  c) If  $P(\text{raas})$  and  $P(\text{fusion})$  and  $\forall a_1, a_2 \in \mathbf{GG}. P(a_1) \wedge P(a_2) \implies P((\text{senior}, a_1, a_2))$  then  $\forall a \in \mathbf{GG}. P(a)$ .
- d) If  $\forall a_1, a_2 \in \mathbf{GG}. P(\text{raas}) \wedge P(\text{fusion}) \wedge P(a_1) \wedge P(a_2) \implies P((\text{senior}, a_1, a_2))$  then  $\forall a \in \mathbf{GG}. P(a)$ .

3. Let  $\longleftrightarrow^*$  be the reflexive symmetric transitive closure of the small-step IMP relation  $\longrightarrow$ . That is,  $\longleftrightarrow^*$  is the smallest relation such that all the following properties hold:

- (Contains  $\longrightarrow$ ) For all  $\langle c, \sigma \rangle$  and  $\langle c', \sigma' \rangle$ , if  $\langle c, \sigma \rangle \longrightarrow \langle c', \sigma' \rangle$  then  $\langle c, \sigma \rangle \longleftrightarrow^* \langle c', \sigma' \rangle$ .
- (Reflexive) For all  $\langle c, \sigma \rangle$ , we have  $\langle c, \sigma \rangle \longleftrightarrow^* \langle c, \sigma \rangle$ .
- (Symmetric) For all  $\langle c, \sigma \rangle$  and  $\langle c', \sigma' \rangle$ , if  $\langle c, \sigma \rangle \longleftrightarrow^* \langle c', \sigma' \rangle$  then  $\langle c', \sigma' \rangle \longleftrightarrow^* \langle c, \sigma \rangle$ .
- (Transitive) For all  $\langle c, \sigma \rangle$ ,  $\langle c', \sigma' \rangle$ , and  $\langle c'', \sigma'' \rangle$ , if  $\langle c, \sigma \rangle \longleftrightarrow^* \langle c', \sigma' \rangle$  and  $\langle c', \sigma' \rangle \longleftrightarrow^* \langle c'', \sigma'' \rangle$  then  $\langle c, \sigma \rangle \longleftrightarrow^* \langle c'', \sigma'' \rangle$ .

Let  $\sigma_0$  be the store that maps all program variables to zero. (See Appendix B for the small-step operational semantics of IMP.)

Which *one* of the following relationships does **NOT** hold?

- a)  $\langle \text{foo} := 42, \sigma_0 \rangle \longleftrightarrow^* \langle \text{foo} := 35 + 7 + 0, \sigma_0 \rangle$
- b)  $\langle \text{if } 0 < \text{foo} \text{ then bar} := 42 \text{ else skip}, \sigma_0 \rangle \longleftrightarrow^* \langle \text{skip}, \sigma_0 \rangle$
- c)  $\langle \text{bar} := 20 + 7, \sigma_0 \rangle \longleftrightarrow^* \langle \text{bar} := 5 + 22, \sigma_0 \rangle$
- $\Rightarrow$  d)  $\langle \text{if } 0 < \text{foo} \text{ then bar} := 42 \text{ else foo} := 42, \sigma_0 \rangle \longleftrightarrow^* \langle \text{if } 0 < \text{foo} \text{ then foo} := 42 \text{ else bar} := 42, \sigma_0 \rangle$

4. Consider the large-step evaluation of the IMP command **while**  $\text{foo} < \text{bar}$  **do**  $\text{foo} := \text{foo} + 1$ . Which *one* of the following statements is true? (See Appendix B for the large-step operational semantics of IMP.)

- a) There do not exist stores  $\sigma$  and  $\sigma'$  such that  $\langle \text{while } \text{foo} < \text{bar} \text{ do } \text{foo} := \text{foo} + 1, \sigma \rangle \Downarrow \sigma'$ .
- b) There exists a store  $\sigma$  such that for all stores  $\sigma'$  it is not the case that  $\langle \text{while } \text{foo} < \text{bar} \text{ do } \text{foo} := \text{foo} + 1, \sigma \rangle \Downarrow \sigma'$ .
- c) For all stores  $\sigma$  and  $\sigma'$  there is a derivation that  $\langle \text{while } \text{foo} < \text{bar} \text{ do } \text{foo} := \text{foo} + 1, \sigma \rangle \Downarrow \sigma'$ .
- $\Rightarrow$  d) For all stores  $\sigma$  there exists a store  $\sigma'$  such that  $\langle \text{while } \text{foo} < \text{bar} \text{ do } \text{foo} := \text{foo} + 1, \sigma \rangle \Downarrow \sigma'$ .

5. Consider two languages: (1) the language of arithmetic expressions (see Appendix A) and (2) the IMP language (see Appendix B). Circle all the ways to prove the determinism of their large-step evaluation.

Determinism for (1): For all expressions  $e \in \mathbf{Exp}$ , stores  $\sigma, \sigma_1, \sigma_2 \in \mathbf{Store}$  and numbers  $n_1, n_2 \in \mathbf{Int}$ , if  $\langle e, \sigma \rangle \Downarrow \langle n_1, \sigma_1 \rangle$  and  $\langle e, \sigma \rangle \Downarrow \langle n_2, \sigma_2 \rangle$  then  $n_1 = n_2$  and  $\sigma_1 = \sigma_2$ .

Determinism for (2): For all commands  $c \in \mathbf{Com}$  and stores  $\sigma, \sigma_1, \sigma_2 \in \mathbf{Store}$ , if  $\langle c, \sigma \rangle \Downarrow \sigma_1$  and  $\langle c, \sigma \rangle \Downarrow \sigma_2$  then  $\sigma_1 = \sigma_2$ .

- $\Rightarrow$  a) By structural induction over the expression for (1).
- b) By structural induction over the command for (2).
- $\Rightarrow$  c) By induction over one large-step derivation for (1).
- $\Rightarrow$  d) by induction over one large-step derivation for (2).

6. Consider the IMP configuration  $\langle \text{while true do foo} := \text{foo} + 1, \sigma_0 \rangle$  where store  $\sigma_0$  maps all program variables to zero.

True or false: There exists a command  $c'$  and store  $\sigma$  such that

$$\langle \text{while true do foo} := \text{foo} + 1, \sigma_0 \rangle \longrightarrow \langle c', \sigma \rangle.$$

$\Rightarrow$  a) True

b) False

7. Suppose we extended the IMP language with a **while**  $b$  **do**  $c_1$  **else**  $c_2$  construct. Intuitively, it behaves similarly to the loop **while**  $b$  **do**  $c_1$ , except that if the loop executes zero times, then command  $c_2$  is executed. Here are the large-step inference rules for the new construct.

$$\frac{\langle b, \sigma \rangle \Downarrow \text{false} \quad \langle c_2, \sigma \rangle \Downarrow \sigma'}{\langle \text{while } b \text{ do } c_1 \text{ else } c_2, \sigma \rangle \Downarrow \sigma'} \quad \frac{\langle b, \sigma \rangle \Downarrow \text{true} \quad \langle \text{while } b \text{ do } c_1, \sigma \rangle \Downarrow \sigma'}{\langle \text{while } b \text{ do } c_1 \text{ else } c_2, \sigma \rangle \Downarrow \sigma'}$$

Which *one* of the following small step inference rules will extend the small-step semantics to be equivalent to the large-step semantics?

a)  $\frac{}{\langle \text{while } b \text{ do } c_1 \text{ else } c_2, \sigma \rangle \longrightarrow \langle \text{if } b \text{ then } (\text{while } b \text{ do } c_1 \text{ else } c_2) \text{ else } c_2, \sigma \rangle}$

b)  $\frac{}{\langle \text{while } b \text{ do } c_1 \text{ else } c_2, \sigma \rangle \longrightarrow \langle \text{if } b \text{ then } (c_2; \text{while } b \text{ do } c_1 \text{ else } c_2) \text{ else } c_2, \sigma \rangle}$

c)  $\frac{}{\langle \text{while } b \text{ do } c_1 \text{ else } c_2, \sigma \rangle \longrightarrow \langle \text{while } b \text{ do } (\text{if } b \text{ then } c_1 \text{ else } c_2), \sigma \rangle}$

$\Rightarrow$  d)  $\frac{}{\langle \text{while } b \text{ do } c_1 \text{ else } c_2, \sigma \rangle \longrightarrow \langle \text{if } b \text{ then } (\text{while } b \text{ do } c_1) \text{ else } c_2, \sigma \rangle}$

8. Which *one* expression is alpha-equivalent to  $(\lambda x. x y) (\lambda z. z)$ ?

$\Rightarrow$  a)  $(\lambda x. x y) (\lambda y. y)$

b)  $(\lambda x. x w) (\lambda z. z)$

c)  $\lambda x. x y \lambda z. z$

d)  $(\lambda z. z) y$

9. Consider the small-step operational semantics of the language of arithmetic expressions (Appendix A). Assuming an initial store that maps all variables to zero, how many steps does the following program take to reach a final configuration?

$$x := (\text{bar} \times (\text{foo} + 3)); y + 2 \times x$$

- a) 3
- ⇒ b) 9
- c) 6
- d) 10

10. Let  $e_1 = \lambda y. f\ 37$ , and let  $e_2 = \lambda y. y + 5$ . What is the result of  $e_1\{e_2/f\}$ ?

- a)  $(\lambda y. y + 5)\ ((\lambda y. ((\lambda y. y + 5)\ 35))\ 2)$
- ⇒ b)  $\lambda y. (\lambda y. y + 5)\ 37$
- c)  $(\lambda y. y + 5)\ 37$
- d)  $\lambda y. 37 + 5$

11. Suppose we extend the arithmetic language with division operation. That is, extend the grammar shown in Appendix ?? with division:

$$e ::= \dots | e_1 / e_2$$

The large-step rule for division is:

$$\text{DIV} \frac{e_1 \Downarrow n_1 \quad e_2 \Downarrow n_2}{e_1 / e_2 \Downarrow n} \text{ where } n = n_1 / n_2 \text{ and } n_2 \neq 0$$

Which **one** of the following is true?

- a)  $0/0$  is syntactically not correct.
- ⇒ b)  $0/0$  is syntactically correct but the evaluation gets stuck for all stores.
- c)  $0/0$  is syntactically correct and yields an answer when evaluated under some stores.
- d)  $0/0$  is syntactically correct and yields NaN (not a number) when evaluated under any store.

12. Consider the following rules for the inductive set, **MySet**

$$\text{RULE1} \frac{}{3 \in \mathbf{MySet}} \quad \text{RULE2} \frac{}{7 \in \mathbf{MySet}} \quad \text{RULE3} \frac{a \in \mathbf{MySet} \quad b \in \mathbf{MySet}}{c = a + b + 5} \quad c \in \mathbf{MySet}$$

Student-A wants to prove that every number in **MySet** is an odd number. Formally, the property Student-A is proving for **MySet** is:

$$P(a) \triangleq \exists i \in \mathbb{Z}. a = 2i + 1$$

Student-A decides to use induction to prove this property and has written the following proof of the property:

- Case RULE1: This is an axiom. We know that  $a \equiv 3$ . Let  $i = 1$ . As  $2 \cdot 1 + 1 = 3$ , we have shown the existence of an  $i$  and shown the property holds.
- Case RULE2: This is an axiom. We know that  $a \equiv 7$ . Let  $i = 3$ . As  $2 \cdot 3 + 1 = 7$ , we have shown the existence of an  $i$  and shown the property holds.
- Case RULE3: This is an inductive case. The inductive hypothesis is that  $P(a)$  and  $P(b)$ . We want to show  $P(c)$  holds. By  $P(a)$  we know that  $a = 2i + 1$  for some  $i$ . By  $P(b)$  we know that  $b = 3$ . We must show that there is a  $k$  such that  $c = 2k + 1$ . We also know by inversion of RULE3 that  $c = a + b + 5$ . Substituting in values of  $a$  and  $b$  gives us  $c = 2i + 1 + 3 + 5$ . Reducing yields  $c = 2i + 9$ . Rewriting gives us  $c = 2(i + 4) + 1$ . Thus, by the existence of  $i + 4$ ,  $P(c)$  holds which is what we aimed to show.

Student-A's TA points out a mistake in Student-A's proof. Which of the following is an error in the proof?

- a) Case RULE2 is not an axiom
- b) We cannot use inversion on RULE3
- c) The inductive hypothesis is applied incorrectly to  $a$  in Case RULE3
- ⇒ d) The inductive hypothesis is applied incorrectly to  $b$  in Case RULE3.

13. Consider the following OCaml code that defines an arithmetic expression and evaluates it.

```

type exp =
  | EVar of string
  | EInt of int
  | EAdd of exp * exp
  | EMul of exp * exp
;;

let rec eval e env =
  match e with
  | EVar x -> env x
  | EInt n -> n
  | EAdd (e1,e2) -> (eval e1 env) + (eval e2 env)
  | EMul (e1,e2) -> (eval e1 env) * (eval e2 env)
;;

```

If you enter the above program in **utop**, you will notice that the type of `eval` is `exp → (string → int) → int`. That is,

```

utop# eval;;
- : exp → (string → int) → int = <fun>

```

Now let us try to run the following command:

```

utop# eval (EVar "x") (fun x → None);;

```

Which of the following is true about the last line?

- a) The last statement issues a type checking error as it cannot infer the type of `env` used in function `eval`.
- ⇒ b) The last statement issues a type checking error due to the following:
  - i. The type of `(fun x → None)` is `string → 'a option`.
  - ii. The type of `env` in the function `eval` is `string → int`.
  - iii. The types of caller and callee arguments mismatch.
- c) The last statement issues a type checking error as it cannot find the key `x`.
- d) None of the above.

## Descriptive Questions

### 1 Small-step operational semantics

Consider the small-step operational semantics for the language of arithmetic expressions (Lecture 3). Let  $\sigma_0$  be a store that maps all program variables to zero.

- (a) Show a derivation that  $\langle 3 + (5 \times \text{bar}), \sigma_0 \rangle \longrightarrow \langle 3 + (5 \times 0), \sigma_0 \rangle$ .

**Answer:**

$$\text{RADD} \frac{\text{RMUL} \frac{\text{VAR} \frac{\langle \text{bar}, \sigma_0 \rangle \longrightarrow \langle 0, \sigma_0 \rangle}{\langle 5 \times \text{bar}, \sigma_0 \rangle \longrightarrow \langle 5 \times 0, \sigma_0 \rangle}}{\langle 3 + (5 \times \text{bar}), \sigma_0 \rangle \longrightarrow \langle 3 + (5 \times 0), \sigma_0 \rangle}}{\langle 3 + (5 \times \text{bar}), \sigma_0 \rangle \longrightarrow \langle 3 + (5 \times 0), \sigma_0 \rangle}}$$

- (b) What is the sequence of configurations that  $\langle \text{foo} := 5; (\text{foo} + 2) \times 7, \sigma_0 \rangle$  steps to? (You don't need to show the derivations for each step, just show what configuration  $\langle \text{foo} := 5; (\text{foo} + 2) \times 7, \sigma_0 \rangle$  steps to in one step, then two steps, then three steps, and so on, until you reach a final configuration.)

**Answer:**

$$\begin{aligned} & \langle \text{foo} := 5; (\text{foo} + 2) \times 7, \sigma_0 \rangle \\ \longrightarrow & \langle (\text{foo} + 2) \times 7, \sigma_0[\text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle (5 + 2) \times 7, \sigma_0[\text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle 7 \times 7, \sigma_0[\text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle 49, \sigma_0[\text{foo} \mapsto 5] \rangle \end{aligned}$$

- (c) Find an integer  $n$  and store  $\sigma'$  such that  $\langle ((6 + (\text{foo} := (\text{bar} := 3; 5); 1 + \text{bar})) + \text{bar}) \times \text{foo}, \sigma_0 \rangle \longrightarrow^* \langle n, \sigma' \rangle$ .

**Answer:** Let's step through the execution of the configuration, to find a final configuration.

$$\begin{aligned} & \langle ((6 + (\text{foo} := (\text{bar} := 3; 5); 1 + \text{bar})) + \text{bar}) \times \text{foo}, \sigma_0 \rangle \\ \longrightarrow & \langle ((6 + (\text{foo} := 5; 1 + \text{bar})) + \text{bar}) \times \text{foo}, \sigma_0[\text{bar} \mapsto 3] \rangle \\ \longrightarrow & \langle ((6 + (1 + \text{bar})) + \text{bar}) \times \text{foo}, \sigma_0[\text{bar} \mapsto 3, \text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle ((6 + (1 + 3)) + \text{bar}) \times \text{foo}, \sigma_0[\text{bar} \mapsto 3, \text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle ((6 + 4) + \text{bar}) \times \text{foo}, \sigma_0[\text{bar} \mapsto 3, \text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle (10 + \text{bar}) \times \text{foo}, \sigma_0[\text{bar} \mapsto 3, \text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle (10 + 3) \times \text{foo}, \sigma_0[\text{bar} \mapsto 3, \text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle 13 \times \text{foo}, \sigma_0[\text{bar} \mapsto 3, \text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle 13 \times 5, \sigma_0[\text{bar} \mapsto 3, \text{foo} \mapsto 5] \rangle \\ \longrightarrow & \langle 65, \sigma_0[\text{bar} \mapsto 3, \text{foo} \mapsto 5] \rangle \end{aligned}$$

- (d) Is the relation  $\longrightarrow$  reflexive? Is it symmetric? Is it anti-symmetric? Is it transitive?

(For each of these questions, if the answer is "no", what is a suitable counterexample? If any of the answers are "yes", think about how you would prove it.)

**Answer:** The relation  $\longrightarrow$  is not reflexive. A relation  $R$  is reflexive if for all  $x$  in the domain of  $R$  we have  $x R x$ . Consider, for example,  $\langle 42, \sigma_0 \rangle$ . It is not the case that  $\langle 42, \sigma_0 \rangle \longrightarrow \langle 42, \sigma_0 \rangle$ , and so  $\longrightarrow$  is not reflexive. The relation  $\longrightarrow$  is not symmetric. A relation  $R$  is symmetric if for all  $x, y$  such that  $x R y$  we have  $y R x$ . Consider, for example,  $\langle 39 + 3, \sigma_0 \rangle$  and  $\langle 42, \sigma_0 \rangle$ . We have  $\langle 39 + 3, \sigma_0 \rangle \longrightarrow \langle 42, \sigma_0 \rangle$  but we do not have  $\langle 42, \sigma_0 \rangle \longrightarrow \langle 39 + 3, \sigma_0 \rangle$ . So  $\longrightarrow$  is not symmetric.

The relation  $\longrightarrow$  is anti-symmetric. A relation  $R$  is anti-symmetric if for all distinct  $x$  and  $y$  we do not have both  $x R y$  and  $y R x$ . In our setting, if we have (distinct) configurations  $\langle e, \sigma \rangle$  and  $\langle e', \sigma' \rangle$  such that  $\langle e, \sigma \rangle \longrightarrow \langle e', \sigma' \rangle$ , then we do not have that  $\langle e', \sigma' \rangle \longrightarrow \langle e, \sigma \rangle$ .

Here is one way to prove this. If we did have distinct configurations  $\langle e, \sigma \rangle$  and  $\langle e', \sigma' \rangle$  such that  $\langle e, \sigma \rangle \longrightarrow \langle e', \sigma' \rangle$  and  $\langle e', \sigma' \rangle \longrightarrow \langle e, \sigma \rangle$ , then we could construct an infinite sequence of small steps:

$$\langle e, \sigma \rangle \longrightarrow \langle e', \sigma' \rangle \longrightarrow \langle e, \sigma \rangle \longrightarrow \langle e', \sigma' \rangle \longrightarrow \langle e, \sigma \rangle \longrightarrow \langle e', \sigma' \rangle \longrightarrow \dots$$

But this would contradict the property that all programs in our language of arithmetic expressions with assignments terminate!

The relation  $\longrightarrow$  is not transitive. A relation  $R$  is transitive if for all  $x, y, z$ , if  $x R y$  and  $y R z$  then  $x R z$ . Consider the configurations  $\langle (2 + 3) \times 7, \sigma_0 \rangle$  and  $\langle 5 \times 7, \sigma_0 \rangle$  and  $\langle 42, \sigma_0 \rangle$ . We have  $\langle (2 + 3) \times 7, \sigma_0 \rangle \longrightarrow \langle 5 \times 7, \sigma_0 \rangle$  and  $\langle 5 \times 7, \sigma_0 \rangle \longrightarrow \langle 42, \sigma_0 \rangle$  but we do not have  $\langle (2 + 3) \times 7, \sigma_0 \rangle \longrightarrow \langle 42, \sigma_0 \rangle$ .

## 2 Large-step operational semantics

Consider the large-step operational semantics for the language of arithmetic expressions (Lecture 4). Let  $\sigma_0$  be a store that maps all program variables to zero.

- (a) Show a derivation that  $\langle 3 + (5 \times \text{bar}), \sigma_0 \rangle \Downarrow \langle 3, \sigma_0 \rangle$ .

**Answer:**

$$\frac{\frac{\langle 3, \sigma_0 \rangle \Downarrow \langle 3, \sigma_0 \rangle}{\langle 3 + (5 \times \text{bar}), \sigma_0 \rangle \Downarrow \langle 3, \sigma_0 \rangle} \quad \frac{\frac{\langle 5, \sigma_0 \rangle \Downarrow \langle 5, \sigma_0 \rangle \quad \langle \text{bar}, \sigma_0 \rangle \Downarrow \langle 0, \sigma_0 \rangle}{\langle 5 \times \text{bar}, \sigma_0 \rangle \Downarrow \langle 0, \sigma_0 \rangle}}{\langle 3 + (5 \times \text{bar}), \sigma_0 \rangle \Downarrow \langle 3, \sigma_0 \rangle}$$

- (b) Find an integer  $n$  and store  $\sigma'$  such that  $\langle \text{foo} := 5; (\text{foo} + 2) \times 7, \sigma_0 \rangle \Downarrow \langle n, \sigma' \rangle$ .

If you have time and a big piece of paper, give the derivation of  $\langle \text{foo} := 5; (\text{foo} + 2) \times 7, \sigma_0 \rangle \Downarrow \langle n, \sigma' \rangle$ .

**Answer:** We have  $\langle \text{foo} := 5; (\text{foo} + 2) \times 7, \sigma_0 \rangle \Downarrow \langle 49, \sigma_0[\text{foo} \mapsto 5] \rangle$ .

In the following derivation, let  $\sigma' = \sigma_0[\text{foo} \mapsto 5]$ .

$$\frac{\frac{\langle 5, \sigma_0 \rangle \Downarrow \langle 5, \sigma_0 \rangle}{\langle \text{foo} := 5; (\text{foo} + 2) \times 7, \sigma_0 \rangle \Downarrow \langle 49, \sigma' \rangle} \quad \frac{\frac{\frac{\langle \text{foo}, \sigma' \rangle \Downarrow \langle 5, \sigma' \rangle \quad \langle 2, \sigma' \rangle \Downarrow \langle 2, \sigma' \rangle}{\langle \text{foo} + 2, \sigma' \rangle \Downarrow \langle 7, \sigma' \rangle} \quad \langle 7, \sigma' \rangle \Downarrow \langle 7, \sigma' \rangle}{\langle (\text{foo} + 2) \times 7, \sigma' \rangle \Downarrow \langle 49, \sigma' \rangle}}{\langle \text{foo} := 5; (\text{foo} + 2) \times 7, \sigma_0 \rangle \Downarrow \langle 49, \sigma' \rangle}$$

- (c) Is the relation  $\Downarrow$  reflexive? Is it symmetric? Is it anti-symmetric? Is it transitive?

(For each of these questions, if the answer is “no”, what is a suitable counterexample? If any of the answers are “yes”, think about how you would prove it.)

**Answer:** The relation  $\Downarrow$  is not reflexive. A relation  $R$  is reflexive if for all  $x$  in the domain of  $R$  we have  $x R x$ . Consider, for example,  $\langle 3 + 4, \sigma_0 \rangle$ . It is not the case that  $\langle 3 + 4, \sigma_0 \rangle \Downarrow \langle 3 + 4, \sigma_0 \rangle$ , and so  $\Downarrow$  is not reflexive.

The relation  $\Downarrow$  is not symmetric. A relation  $R$  is symmetric if for all  $x, y$  such that  $x R y$  we have  $y R x$ . Consider, for example,  $\langle 39 + 3, \sigma_0 \rangle$  and  $\langle 42, \sigma_0 \rangle$ . We have  $\langle 39 + 3, \sigma_0 \rangle \Downarrow \langle 42, \sigma_0 \rangle$  but we do not have  $\langle 42, \sigma_0 \rangle \Downarrow \langle 39 + 3, \sigma_0 \rangle$ . So  $\Downarrow$  is not symmetric.

The relation  $\Downarrow$  is not anti-symmetric. A relation  $R$  is anti-symmetric if for all distinct  $x$  and  $y$  we do not have both  $x R y$  and  $y R x$ . In our setting, if we have (distinct) configurations  $\langle e, \sigma \rangle$  and  $\langle n, \sigma' \rangle$  such that  $\langle e, \sigma \rangle \Downarrow \langle n, \sigma' \rangle$  and  $e'$  is not an integer, then we do not have that  $\langle n, \sigma' \rangle \Downarrow \langle e, \sigma \rangle$ .

This can be proven by inspection of the rules, or by induction on the derivation of  $\langle e, \sigma \rangle \Downarrow \langle n, \sigma' \rangle$ .

The relation  $\Downarrow$  is transitive. A relation  $R$  is transitive if for all  $x, y, z$ , if  $x R y$  and  $y R z$  then  $x R z$ . To prove this, suppose that  $\langle e, \sigma \rangle \Downarrow \langle e', \sigma' \rangle$  and  $\langle e', \sigma' \rangle \Downarrow \langle e'', \sigma'' \rangle$ . By examination of the rules, we have that  $e'$  is an integer. Thus, by the rule INT we have  $\langle e', \sigma' \rangle \Downarrow \langle e', \sigma' \rangle$ . Moreover, by the determinism of the arithmetic language (which we discussed in Lecture 2), we have that  $e' = e''$  and  $\sigma' = \sigma''$ . Thus we have that  $\langle e, \sigma \rangle \Downarrow \langle e'', \sigma'' \rangle$  as required.

## Appendix A Semantics for the language of arithmetic expressions
